Tel: Mex 001 800 738 7610 • Tel: DE +49 6571 105 308 • Tel: CN +86 10 8565 4566

Conventions used in this manual

This manual includes safety precautions and other important information in the following format:

**NOTE**: Provides helpful supplementary information.

**IMPORTANT**: Provides instructions to avoid damaging hardware or a potential hazard to the environment, for example: fuel leakage from equipment that could harm the environment.

⚠️ **CAUTION**: Indicates a potentially hazardous situation that could result in minor or moderate injury if not avoided. This may also be used to alert against unsafe practices.

⚠️ **WARNING**: Indicates a potentially hazardous situation that could result in severe injury or death if not avoided.

⚠️ **DANGER**: Indicates an imminently hazardous situation that will result in death if not avoided.

Operating precautions

FFS equipment is designed to be installed in areas where volatile liquids such as gasoline and diesel fuel are present. Working in such a hazardous environment presents a risk of severe injury or death if you do not follow standard industry practices and the instructions in this manual. Before you work with or install the equipment covered in this manual, or any related equipment, read this entire manual, particularly the following precautions:

⚠️ **CAUTION**: Use only original FFS parts. Substituting non-FFS parts could cause the device to fail, which could create a hazardous condition and/or harm the environment.

⚠️ **WARNING**: Follow all codes that govern how you install and service this product and the entire system. Always lock out and tag electrical circuit breakers while installing or servicing
this equipment and related equipment. A potentially lethal electrical shock hazard and the possibility of an explosion or fire from a spark can result if the electrical circuit breakers are accidentally turned on while you are installing or servicing this product. Refer to this manual (and documentation for related equipment) for complete installation and safety information.

⚠️ **WARNING:** Before you enter a containment sump, check for the presence of hydrocarbon vapors. Inhaling these vapors can make you dizzy or unconscious, and if ignited, they can explode and cause serious injury or death. Containment sumps are designed to trap hazardous liquid spills and prevent environmental contamination, so they can accumulate dangerous amounts of hydrocarbon vapors. Check the atmosphere in the sump regularly while you are working in it. If vapors reach unsafe levels, exit the sump and ventilate it with fresh air before you resume working. Always have another person standing by for assistance.

⚠️ **WARNING:** Follow all federal, state, and local laws governing the installation of this product and its associated systems. When no other regulations apply, follow NFPA codes 30, 30A, and 70 from the National Fire Protection Association. Failure to follow these codes could result in severe injury, death, serious property damage, and/or environmental contamination.

⚠️ **WARNING:** Always secure the work area from moving vehicles. The equipment in this manual is usually mounted underground, so reduced visibility puts service personnel working on it in danger from moving vehicles that enter the work area. To help prevent this safety hazard, secure the area by using a service truck (or some other vehicle) to block access to the work area.

⚠️ **WARNING:** UPP® Welding Units must never be operated in Zone 1 or Zone 0 areas (Hazardous area definitions are from European Directive 1999/92/EC and guidelines can be found in the APEA Blue Book 3rd Edition).

⚠️ **WARNING:** Ensure Welding Units are connected to a power supply that meets the requirements detailed in the user manual and are within the requirements of any local authority or regional legislation.

⚠️ **WARNING:** Important to any type of piping system is to safely connect all metallic components to ground. Metallic components, and more general conductive materials, due to their high capacitance, can have the potential to store high amount of electrostatic energy (sparks discharge can only be observed over conductive elements).

⚠️ **WARNING:** All exposed metal parts used in UPP® System installations should be adequately grounded to a dedicated earth electrode and brought to a potential equal to that of other metal parts in the close proximity.

⚠️ **WARNING:** Where using chemicals (such as Acetone) during the installation of UPP® systems products, follow all safety guidelines given on the chemical containers themselves or on any accompanying literature.

⚠️ **WARNING:** Some installation of UPP® products may occur in confined spaces where a lack of oxygen and a concentration of toxic vapors is likely to be experienced.

⚠️ **WARNING:** Such working conditions are dangerous and all local health and safety guidelines for working in such environments should be followed.

⚠️ **WARNING:** Ensure the correct personal protective equipment (PPE) is used at all times in line with local health and safety requirements.
**WARNING:** Ensure all safety data is accessed and used while installing UPP® Systems (Material Safety Data Sheets are available in the download area of the UPP® website).

**WARNING:** UPP® products should be transported and stored in accordance with the guidelines contained in this manual.

**WARNING:** Heavy items should be handled using suitable lifting equipment operated by authorised personnel.

**DANGER:** Make sure you check the installation location for potential ignition sources such as flames, sparks, radio waves, ionizing radiation, and ultrasound sonic waves. If you identify any potential ignition sources, you must make sure safety measure are implemented.

### Site Preparation

**IMPORTANT:** Site inspection: Make sure the site is prepared and ready. The tanks, sumps, fill points, vents etc. should be in place.

**IMPORTANT:** The site should be free from previous fuel contamination.
Several types of UPP® underground fuel pipe are available for different applications and to meet various engineering and legal requirements:

- Primary pipe can be used as a fuel-proof liner for product, suction, pressure, vapor vent, and fill lines.
- Secondary containment pipe can be used with EN primary pipe for pressure systems or environmentally sensitive sites.
- Integral secondary containment pipe (UL971 spec) can be used for pressure systems or environmentally sensitive sites.
- Electrical conduit pipe can be used for underground electrical wiring protection.
- Duct can provide a watertight, underground channel for pipes or electrical cables.

UPP® piping systems are designed in various diameters, from 32-160mm (I-6") to transfer fuels in filling station forecourts, marinas, and airports. UPP® systems are also used for government and military installations as well as many industrial sites such as mines and rail depots.
There is no requirement for a concrete trench because fusion welded HDPE pipe is structurally resistant to weight of backfill material and dynamic traffic loads. Over 30 years experience showing no failures in underground fuel pipe systems and no loss into the ground.

**Underground Fuel Pipe Construction**

The black outer structural layer of the pipe is High Density Polyethylene (HDPE), grade PE100 that allows the use of electrofusion couplers and fittings to construct a variety of pipeline configurations. HDPE PE100 has well-proven resistance to: stress cracking, puncture, scratch, impact, microbial and rodent attack.

The intermediate tie-layer causes a permanent bond to occur between the polyethylene and the liner material. The liner of UPP® primary pipe is a specially formulated “fuel proof” barrier layer manufactured from EVOH (EN/UL). This liner has exceptional resistance to absorption and permeation of both hydrocarbon and alcohol fuel blends.

The smooth bore and low friction loss of UPP® pipe permits higher fuel and vapor flows than steel pipe, reducing the pumping energy costs.

UPP® primary fuel pipe is pressure rated to 10 bar (EN) or (90 psi) to UL971. Rupture pressure is typically exceeding 40 bar (580 psi) providing a large margin of safety.

</table>

Table 2: EN14125 Pipe Maximum Pressure Rating
Transit, Off-Loading, and Storage

Although UPP® polyethylene pipe and fittings are extremely hard wearing and resilient, it is important to handle and store them with care to prevent scuffing or gouging. Any damaged pipes may need to be rejected and not installed.

UPP® products should be transported in a flat-bedded vehicle, free from sharp objects and projections. Wide polypropylene slings must be used when lifting pipe crates by crane. Avoid using chains, hooks or hawsers. A spreading beam should be used when lifting crates containing pipe lengths greater than 6m (19ft 8"):

- Allow for a slight bending of the pipe crates when on and off-loading.
- Standard 6m (19ft 8") crates may be moved using a forklift. A side loader fitted with a minimum of four supporting forks should be used for longer lengths. Otherwise use a crane fitted with a spreader beam.
- When using a forklift to on or off-load coils, the forks should be covered to avoid damage to the coiled pipe.

Figure 3: Moving Coils
Storage on site

- Individual pipe lengths should be stacked not more than 1 m (3 ft) high with the bottom layer fully restrained by wedges. The bottom layer of pipes should be laid on timber battens at 1 m (3 ft) centres to avoid any damage from sharp objects lying on the ground.

- Pipe crates should be stored on clear, level ground and should never be stacked more than three crates high.

- Coils should be stored on firm level ground that has suitable protection for the bottom of the coil. Primary pipe can be stacked four coils high, but EN double wall pipe should never be stacked more than three coils high. Individual coils should be stacked flat. If stored on edge, they must be secured against a properly anchored support and stored like this for a short period of time only, particularly in warm weather conditions.

- Badly stacked coils and pipe lengths can slip causing personal injury or damage to the product. Facilities for safe lifting and moving must be available.

- Pipes are supplied with end caps to prevent entry of any contamination. These end caps must be kept in place during storage.

- UPP® fittings: All electrofusion fittings are packed in heat-sealed polyethylene bags and delivered in cardboard cartons. Fittings should be stored in their packaging and in a dry area, away from direct sunlight, until ready for use. This is particularly important for electrofusion fittings. These must be kept in their packaging until ready for use to prevent any contamination or oxidation.

Uncoiling Pipe

Figure 4: Uncoiling Pipe
**CAUTION:** The pipe can straighten with considerable force. Take care when releasing pipe from the coil and secure the straightened pipe.

Let the pipe rest in its uncoiled state for about eight hours. High ambient temperatures can reduce this “layout” time and low temperatures may increase it. Pipe can be laid in its final position to “relax” before connecting up.

- You need at least three people to uncoil and cut pipe. The coil is taped up in layers to make it easier to uncoil at manageable intervals.
- The area in which the pipe is uncoiled on site must be clear, safe and free of sharp objects.
- Remove the tape around the tail end on the outer winding and secure this end.
- With the coil in the vertical position, roll the coil out cutting and removing tape as you find it (ensuring to release only the next turn of pipe in the coil).
- Do not drag the pipe.
- The natural curves from coiling can be used to change pipe direction and bags of sand, pea gravel or stakes can be used to hold it in place until it is ready for connecting.
- One person should hold the pipe whilst another cuts it to the desired length.
- The cut ends will have a prominent hook that can be partially removed when weight is placed on it (bags of sand or pea gravel), or use the hook end to your advantage when turning direction into a chamber or pump sump.
Pipe Burial Guidelines

Recommended burial depth of UPP® pipe is a minimum of 300mm (12”).

- All trenches should be sloped back towards the storage tanks. The fall back (slope) for all pipework to the tank chambers should be a minimum of 1 m every 100 m or ¼" per foot (Figure 7). This may vary to meet local requirements. The position of the entry fittings at the furthest dispenser sump away from the tank chambers may be considerably higher than that of the entry fittings on the closest dispenser sump.

- Vapor return lines should have a slope of 2 m every 100 m (¼" per foot) and never less than 1 m every 100 m (¼" per foot) back towards the tank farm, unless in-line joints such as elbows are to be used.

- Trench corners should have a radius of 1.5 m (5’).

- A recommended 150mm (6") bed of backfill material should be laid underneath the pipe prior to installation and there must never be voids under or around the pipe. Acceptable backfill materials are:
  - Well-rounded pea gravel size 3mm (⅛") to 20mm (¾”).
  - Crushed rock size 3mm (⅛”) to 16mm (⅝”).
  - Clean washed sand.
  - At installation, backfill cannot be contaminated with petroleum products or other contaminants.

Figure 5: Pipe Spacing
• When laying duct onto a concrete base a 150mm (6") thick bed of compacted sand should be laid on the concrete, below the duct. (The minimum amount of sand should be 50mm (2") of compacted sand)

• All beds should be laid so that the pipe will not dip or sag when it is installed.

• Laying of pipe should start from the tank farm.

• Any mechanical joints or compression fittings must be located within a containment chamber or sump or be adequately protected from the environment when used on buried vent lines.

**NOTE:** Refer to FFS manual 408001007 for information about the electrofusion process.
• UPP® pipe that is located between dispenser containment or that exceeds 12 m (39 ft) should be laid in a series of large snake-like curves and not in straight lines. Uncoiled pipe, when laid, will settle in a natural curve.
• Generally any thermal expansion will be accounted for by following our guidelines for spacing, backfilling and ensuring runs are “snaked”.

• Pipes should be separated from each other by at least the diameter of the largest pipe.

• If pipe-runs cross each other they must be separated by at least as much backfill material as the diameter of the largest pipe or protected using at least 25 mm (1") of expanded polystyrene.

• If used above ground, UPP® pipe should be protected against mechanical, climatic damage. Additional supports and anchor points may also be required. Check fire codes for proper installation. Also see the document *UPP® Piping Above Ground and Marina Installations*.

• Mark positions on the tank access chamber/sump for penetration locations and install UPP® seals.

**Bend Radius**
The UPP® piping systems have a semi-rigid construction which gives both strength and flexibility. To achieve absolute minimum bend radius in cold conditions, use a heated trailer or equivalent to precondition the pipe. In Figure 9, “X” is the bend radius, the distance between the pipe axis and “+,” the center of the pipe’s arc.

![Bend Radius Diagram]

**Figure 9: Bend Radius**

**NOTE:** Refer to Table 3 for allowable bend radius of UPP® Pipe.

**IMPORTANT:** Completion Records—On completion of UPP® installation make an “as constructed” drawing showing the exact location of all below ground lines. It is also recommended that, in addition, a photographic record is preserved.

**Pipe Bend Radius**

</tr>
</tbody>
</table>

Table 3: Allowable Bend Radius

**Pipe Detector Tape**

UPP® Detectable tape is used to allow the piping location to be found after it has been covered.
The tape is installed below ground at 250mm (9.8 inches) height directly above pipe runs to indicate the position of each pipe.

Both ends of the tape should be grounded during installation.

When using a detection tool, the near end of the detectable tape should be disconnected from the grounding point to allow the red cable from the transmitter to be connected to the tape and
the black cable from the transmitter to be connected to the grounding point. The far end of the tape should remain grounded to give the highest signal strength and the earth spike should be as far away from the trace path as possible at a 90 degree angle.

Use the lowest frequency possible from the transmitter around 577 Hz or 8 KHz to eliminate coupling to other grounded cables. Use the receiver to follow the path of the tape to locate the buried pipe. Follow direction included with the receiver and transmitter for detecting buried pipe location.
Pressure Testing

Following inspection, prior and subsequent to backfilling, a tightness test should be carried out by a competent person on each pipe run, chamber and sump to verify the integrity of joints and seals. This testing should meet the requirements of local officials and engineers and comply with local health and safety regulations. The following testing procedure is suggested for guidance only and should in no way override oil companies or local regulator’s requirements.

Testing Guidelines

**Equipment**

- Target test pressure should be 50% of scale on gauge, e.g. if the test pressure is 1 Bar (14.5 psi), use a 2 Bar (29 psi) gauge.
- Gauges should have serial numbers and be tested and certified every year.
- Pressure testing equipment should have fitted a relief valve set at around 0.5 bar (7.25 psi) above the test pressure.

**General Guidelines**

- When applying pressure from gas cylinders, use suitable valves to ensure test pressure is not exceeded.
- Apply pressure or vacuum slowly to minimise risks.
- When you test primary pipe for tightness, the secondary should be open to atmosphere.
- Secondary pipe should not be welded prior to testing primary to allow inspection of joints.
- When you test secondary pipe for tightness, the primary should be open to atmosphere. (The exception is when you test the secondary pipe at a pressure higher than the recommended value. When this is the case, pressurize the primary pipe to at least 1 bar before you pressurize the secondary pipe.)
- Wipe each joint with soapy water to check for leaking.

⚠️ **CAUTION:**

- To avoid explosion hazards, nitrogen or an inert gas from a pressure cylinder should be used in place of compressed air for tightness testing if fuel has been used to ballast underground storage tanks or if pipe-work has previously contained petroleum.
- Pipe-work should be disconnected (isolated) from underground storage tank prior to commencing tightness testing.
- Any water used for testing should be disposed of through the oil/water separator or by a specialist contractor and in accordance with any local environmental health and safety requirements and regulations.
There are two recommended tightness test methods for UPP® primary pipe-work: hydrostatic and pneumatic. In all instances the hydrostatic method is to be preferred as it allows high pressures to be used with relative safety. However, there will be instances where the introduction of water into the pipe-work is undesirable, in these cases the pneumatic method should be adopted paying particular attention to the safety aspects of working with compressed gas due to the high levels of potential energy that can be stored.

**IMPORTANT:** Always test secondary pipe after you perform the pneumatic procedure.

**Recommended Pipe Test Procedure**

**Primary Pipe Hydrostatic Pressure Testing Method**

**Equipment**

- Pump rated for more than 10 bar (145 psig)
- Hydrofor (reservoir or pressure tank)
- Two pressure gauges, rated for 12 bar (174 psig), min. reading 0.1 bar (2 psig)
- Check valve
- Ball valve
- Pressure relief valve rated for 20 bar (290 psig), set at 11 bar (159 psig)

**Conditioning Phase**

- Fill the pipe work system to be tested with water, making sure that any air relief valves are opened while filling the pipe work.
- After filling the pipe work wait 1 hour for the temperature to stabilize.
- Pressurize the system to 10 bar (145 psi) and maintain this pressure for 30 minutes. (System pressure shall be maintained by means of refilling in order to compensate for the increase in volume due to the expansion of the pipe-work). At this time the system should be thoroughly inspected for leakage. After any such areas have been remedied repeat the conditioning before proceeding to the testing phase.

**Testing Phase**

- Rapidly reduce the system pressure to 3 bar (43.5 psi) by bleeding water from the pipe-work. (Due to the visco-elastic properties of polyethylene the pipe will contract).
- During the test period of 90 minutes the pressure should be recorded with the frequency shown below:

<table>
<thead>
<tr>
<th>Test period (mins)</th>
<th>Frequency of readings (mins)</th>
<th>Number of readings</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-10</td>
<td>2</td>
<td>6</td>
</tr>
<tr>
<td>10-30</td>
<td>5</td>
<td>4</td>
</tr>
<tr>
<td>30-90</td>
<td>10</td>
<td>6</td>
</tr>
</tbody>
</table>

**Table 4: Recording Test Results**

- The test is passed if all the readings during the testing cycle are 3 bar (43.5 psi) or above.
- Decreasing readings = failure of pressure test. (Note that the readings are likely to increase).
If the system fails the pressure test make the following checks:

- Check all mechanical connections.
- Check welded joints.

When the failure point has been located and remedied repeat the full conditioning and testing sequence.

The following testing procedure is suggested for guidance only and should in no way override oil companies or local regulator’s requirements. Never exceed the pressure ratings of components shown on Table 1 and Table 2 when testing.

**Test Procedure**

- Record Temperature and Pressure at start of each test time.
- Condition and test the piping as follows:
  1. Pressurise the piping to 10% of test pressure, hold pressure for 30 minutes and inspect for leakage or pressure drop.
  2. Increase pressure to 50% of test pressure and again inspect for leakage while holding pressure for 30 minutes.
  3. Increase pressure to 100% of test pressure and again inspect for leakage while holding pressure for 30 minutes.
- Record Temperature and Pressure at end of each test time.
- If results are within criteria of Table 6 Tightness Test is passed.

**Pressure Testing Safety**

Follow these guidelines when conducting pneumatic testing:

- Wear Safety glasses.
- Relieve air pressure before any corrective actions are taken.
- Allow only necessary and authorized persons in the proximity of pipe being tested.
- Restrain the movement of connections, joints and seals during testing.

---

### Sump Inspection Register

- **Required monthly and/or annual inspection:** Containment sumps located on the property at which the FFS products are installed must be visually inspected for liquid monthly. Sump sensors if installed, must be tested annually. Any leaks must be corrected at the time they are found.

- **Recommended monthly inspection:** Verify sump lids are tight and sealed. Inspect sumps for dirt, debris, liquid or any physical cracks or holes that would allow leakage. Check for evidence of staining or new staining. Verify penetration boots are in good condition and the pipe entry into the sump is positioned properly (near perpendicular entry). Verify sump liquid sensors are positioned correctly if installed. Verify the piping and other equipment in the sump are in good condition.

- Record any faults on this Sump Inspection Register and have the fault(s) corrected at the time found.

- You can download this form (part number 408001011) from the FFS website at www.franklinfueling.com.

- End user proprietary inspection check register logs or any form to record these inspections is acceptable.
